An overview of the relationships between the individual components of aloe vera and their biological effect

Keywords:
- Medicinal plant
- Unique combination
- Pharmacological interaction

Summary:
Aloe vera is known as a medicinal plant or silent healer. This article addresses the combination of individual and unique active ingredients of aloe vera and their pharmacological interaction.

Aloe vera (Aloe barbadensis Miller) is a perennial succulent belonging to the Liliaceae family, and is called the healing plant or the silent healer. As a result of its use in folk medicine, it is claimed that aloe vera has wound and burn healing properties, and anti-inflammatory, and immunomodulatory effects. Aloe vera is used in a variety of commercial products because of these therapeutic properties. It is being used as a whole extract, however, and the relationship between the components of the extract and its overall effect has not been clarified. A more precise understanding of the biologic activities of these is required to develop aloe vera as a pharmacetical source. Many attempts have been made to isolate single, biologically active components, to examine their effects, and clarify their functional mechanisms. This review focuses on the relationship between the isolated aloe vera components (i.e., glycoproteins, anthraquinones, saccharides, low-molecular-weight substances) and their presumed pharmacologic activities.

A REVIEW ON THE RELATIONSHIP BETWEEN ALOE VERA COMPONENTS AND THEIR BIOLOGIC EFFECTS

Seongwon Choi and Myung-Hee Chung

INTRODUCTION

Aloe vera (Aloe barbadensis Miller) is a perennial succulent belonging to the Liliaceae family. It is a cactus-like plant that grows in hot, dry climates. In nature, it may be damaged physically by ultraviolet (UV) irradiation or by insects. Perhaps its survival in a harsh environment encourages people to believe that aloe vera has wound-healing and antibiotic effects. It is, therefore, less than fortuitous that aloe vera has been reported to possess immunomodulatory, anti-inflammatory, UV protective, antiprostaglandin, and wound- and burn-healing promoting properties. However, previous treatments of such diseases and conditions with aloe vera gel have been empirical rather than theoretical. Therefore, the clarification of the mode of action of the biochemical components of aloe vera is important in the determination of the most efficient way of using such active species effectively and developing their applications. It is essential to establish the relationships between the components of aloe vera and their pharmacologic effects. Many attempts have been made to isolate single, active components to examine their effects and clarify their functional mechanisms. Reynolds's review describes the biologic activ-
ities of several aloe species. Since then, further pharmacologic activities of the components of aloe vera have been reported. Therefore, this review focuses on establishing the relationship between the components of aloe vera and their effects based on published reports and more recent findings.

**Biologic Activities of Aloe Vera Gel**

The whole gel extract of aloe vera has been reported to have various pharmacologic properties, specifically to promote wound, burn, and frost-bite healing, in addition to having antiinflammatory, antifungal, hypoglycemic, and gastrotrope properties. Of those claims, aloe vera's antiinflammatory and wound healing has been the most extensively studied.

Wound healing is considered to be composed of three overlapping events: (1) inflammation, (2) new tissue formation, and (3) matrix remodeling. In the case of whole gel extracts, many clinical trials have been performed on animal models. Protein factors related to wound healing have been investigated, such as growth factors, cell-migration related factors, matrix-forming factors, and matrix-degradation factors. Aloe vera gel extract stimulated fibroblast growth in a synovial model and also enhanced wound tissue strength and collagen turnover in wound tissue. In another trial, topical application of aloe vera gel stimulated fibroblast activity and collagen proliferation, in addition to increasing the content of granulation tissue and tissue crosslinking by increasing the aldehyde content and decreasing the acid solubility. The aloe vera gel also increased levels of hyaluronic acid and dermatan sulphate in granulation tissue. In terms of the formation of new tissue, angiogenesis is essentially required to provide oxygen and metabolites to the tissues. An increase in the blood supply was observed after aloe vera gel treatment, and it has been suggested that an increased oxygen access is one of the factors enhanced by aloe vera gel. Aloe vera gel was found to contain an angiogenic component. The aloe vera gel extract permitted faster healing of burns, and reestablished the vascularity of burn tissue of a guinea pig. Although many reports support the promotion of wound healing by the whole gel extract, several reports have mentioned inhibitory effects. A delay in wound healing was observed when a wound was treated with aloe vera gel. In another trial, aloe vera gel hindered wound healing in an experimentally induced second-degree burn. Different results should be expected, however, given the fact that the composition of the aloe vera gel varies and that even within the same species the plant depends on source, climate, region, and the processing method. Nevertheless, as more factors involved in the wound healing process are discovered, data accumulates supporting the enhancing effect of whole gel.

Other aspects of the pharmacologic activity of aloe vera gel are presented by its antiinflammatory and immunomodulatory effects. Antiinflammation is the first step in the wound healing process. Based on the fact that aloe vera gel effectively enhances wound healing, whole gel was examined for antiinflammatory activity. The whole gel extract was found to have antiinflammatory activity in carrageenan-induced edema in rat paws. Moreover, it was found to enhance wound tensile strength and antiinflammation. Topically administered aloe vera preparations inhibited inflammation in the croton oil-induced edema assay. In terms of the mechanism involved, the inhibitory action of aloe vera gel on the arachidonic acid pathway via cyclooxygenase has been suggested.

The immunomodulatory activity of aloe vera gel has also been widely studied. The topical application of aloe vera gel extract to the skin of UV-irradiated mice improved UV-induced immune suppression. Topical application inhibited contact hypersensitivity and delayed type hypersensitivity suppression by UV radiation in mice. It preserved the number and morphology of irradiated Langerhans and dendritic epidermal cells in skin. Lissou et al demonstrated that the administration of aloe vera with plasmal indole melanin enhances the therapeutic results in patients with advanced solid tumors. The percentage of nonprogressing patients and the percentage of 1-year survival was significantly higher in the group treated with aloe vera plus melanin than in the melanin-only group. It is possible that aloe vera activate antitumor immunity and produce therapeutic benefits in terms of stabilization of disease and survival in patients with advanced solid tumors. Aloe vera gel also showed hypoglycemic activity on insulin-dependent diabetes mellitus and non-insulin-dependent diabetes mellitus rats,
though it was found to be more effective in non-insulin dependent diabetes. The acute and chronic effects of aloe vera gel were studied on the plasma glucose levels of alloxan-diabetic mice and was found to reduce plasma glucose levels. Aloe vera gel has also been found to have antifungal activity and is believed that aloe vera likely contains antibiotic substances to help to prevent infection.

Studies in vitro, using crude gel extracts, are difficult to perform and the results are difficult to interpret because of the complex nature of the active substances. For example, since aloe vera gel contains both inhibitory and stimulatory systems with respect to inflammatory and immune responses, it is possible that several activities operate separately and each has its own part to play in the overall effect. Therefore, the clarification of the modes of action for each individual component of aloe vera is the most efficient way to develop applications for the components of aloe vera.

Glycoproteins

Compared to the other components the glycoproteins have not been extensively studied, especially with respect to wound healing. However, there have been a consistent number of reports regarding biologically active glycoproteins from aloe vera. Several of these reports point to the wound-healing effect of glycoproteins and have attempted to isolate glycoprotein components and found that glycoproteins stimulate cell proliferation. Fractions prepared from aloe vera gel contain lectin-like substances that promote the growth of normal human cells like human fibroblasts. Yagi et al reported on the cell-proliferating activity of a 29 kDa glycoprotein composed of two 14 kDa subunits. This was found to enhance the proliferation of baby hamster kidney cells and normal human dermal fibroblasts.

Recently, Choi et al reported on the proliferation and wound healing effect of a 5.5 kDa glycoprotein. This glycoprotein was isolated by activity-guided sequential fractionation from aloe vera gel and was found to enhance keratinocyte proliferation. The cell-proliferating effect of the glycoprotein was confirmed by accelerated closure of a scratch made on a monolayer of human keratinocytes. Moreover, when this glycoprotein was tested on a three-dimensional raft-culture, it dose-dependently stimulated the formation of epidermal tissue. Furthermore, at the immunohistochemical level, epidermal growth factor receptor, fibronectin receptor, fibronectin, and keratin 5/14 were noticeably expressed. This glycoprotein fraction was found to enhance wound healing in hairless mice by 8 days after injury with significant cell proliferation. This glycoprotein is linked to saccarides, 70% of which is mannanose. Due to a lack of information regarding the amino-acid sequence of glycoproteins isolated from aloe vera, it is not yet known whether the 5.5 kDa glycoprotein is a fragment of longer glycoproteins. Nevertheless, this experiment systematically showed how the 5.5 kDa glycoprotein affects cell proliferation and wound healing both in vivo and in vitro.

Lectin has mitogenic activity and a wound healing effect. Wintera et al. reported that lectins are present in the gel portion of aloe vera leaves. Kolke et al isolated a 35 kDa lectin from aloe aborescens, which was presumed to be either a trimeric or tetrameric form composed of identical subunits with a molecular mass of about 9 kDa. It was also found to be a mannose-binding lectin.

Components of Aloe Vera

Box 1 summarizes the components of aloe vera, which are primarily glycoproteins, anthraquinones, saccarides, and low-molecular-weight substances. Polysaccharides are largely glucose-mannans of various compositions; some are acetylated while others are not. Galactose and galactomannose polymers are also frequently found. Different investigations have reported different polysaccharide structures, which may be due to different geographical origins or to the use of different varieties or subspecies. Acetylated mannan has a range of interesting biologic activities as described below. Recently glycoproteins with cell proliferation-promoting activity have been reported. Aloe-specific anthraquinones are also present and include aloin, aloe-emodin, barbaloin, isobarbaloin, and others. In addition to these, low-molecular-weight substances are reported, such as aloesin, β-sitostanol, diethylxylphthalate, vitamins, and beta-carotene. Apart from technical differences and inconsistencies, it appears that the types and levels of components present in aloe gel vary according to geographic origin or variety, therefore, the identification of the active components of aloe vera is important for the effective use of the plant.
with hemagglutination and mitogenic activities. However, no studies have been conducted regarding the amino sequences of active lectins of aloe vera. Mannose is linked to the active 5.5 kDa glycoprotein at a high percentage, may be a kind of lectin. Another possibility is that the mannosyl exhibit the wound-healing activity when linked to the protein as suggested by Davis et al.33

Davis et al33 tried to determine whether mannosyl phosphate is the active ingredient in aloe vera for wound healing and antiinflammation, and whether binding to a protein is necessary to initiate a growth response. Experiments showed that mannosyl phosphate dose-dependently promotes wound healing. Mannosyl phosphate linked to a protein, thereby forming a mucopolysaccharide, may produce even greater wound-healing effects.34 It is possible that the binding of a ligand at one binding site is capable of influencing ligand binding at another binding site of the same receptor; binding of mannosyl phosphate to its binding site preferentially increases the affinity of insulin-like growth factor II to its binding site.35,36 Then insulin growth factor is delivered to cells and increases fibroblast activity and the wound's healing response. Therefore, the wound healing activity of the reported glycoproteins should be further investigated as protein with and without mannosyl bound.

Aloe vera gel contains a small amount of phenolics in the leaf exudates.37 These phenolics are responsible for reducing the proliferative effect of lectin-like glycoproteins. In addition, conflicting activities of the proliferative glycoproteins and the inhibitory glycoproteins, in combination with phenolic substances in aloe vera gel, may cause the observed variability in the pharmacological results and the therapeutic experiments when whole gel is used in wound healing.

Another research group recently isolated a 10 kDa glycoprotein from aloe vera gel, using an activity-based follow-up method. This glycoprotein was found to have antiallergic activity.37 It reduced histamine release and promoted the synthesis and secretion of leukotrienes simultaneously in activated lung mast cells of the guinea pig. It decreased dose-dependently protein kinase C and phospholipase D activities, inhibited mass diacylglycerol and phospholipase A activity, and blocked Ca^{2+} influx during mast cell activation.

**Anthraquinones**

The allegedly, pharmacologically active anthraquinones of aloe vera are aloin, aloe-emodin, barbitalin, and emodin (see Box 1). Their therapeutic claims are a purgative action, antiinflammatory activity, antiprotozoal action, antioxidant activity and so on (Table 1).

Aloe-emodin and emodin showed synergistic effects with rhein anthrone during purgative activity in mice.38 The purgative action of barbitalin is induced by *Babacterium sp.*, which is capable of

March 1980-1986

Regarding anti-inflammatory and immunomodulatory effects of anthraquinones, one proposed mechanism involves antioxidation. Anthraquinones may act as antioxidants and radical scavengers. Reactive oxygen species and free-radical-mediated reactions are involved in inflammatory response and can contribute to liver necrosis. Histologic analysis of liver specimens showed that inflammatory infiltration of lymphocytes and Kuffer cells was reduced in aloe-emodin treated rats. Aloe-emodin quinone pretreatment reduced the acute liver injury induced by carbon tetrachloride, and aloe-emodin appears to protect against hepatocyte death and the inflammatory response that occurs subsequent to lipid peroxidation. Antioxidant and radical scavenging activity of aloe-emodin was suggested as a protection mechanism against peroxidation of linoleic acid.

Anthraquinones, including aloe-emodin, are known to have antiprotozoal activity. Aloe-emodin elicited dose-dependent growth inhibition of Helicobacter pylori, which is a possible causative factor of gastric cancer. Aloe-emodin may act like a noncompetitive inhibitor of aryamine N-acetyltransferase activity, thereby decreasing effects of aryamine carcinogens in inducing carcinogenesis. In addition, antibiotic factors are released by the healing tissues in response to aloe treatment.

Aloe-emodin possesses contradictory activities on cell growth. It was found to stimulate the growth of primary rat hepatocytes and caused a 2.5-fold increase in DNA synthesis in primary rat hepatocytes. However, there are other controversial observations. Aloe-emodin was found to have cell death or apoptosis-inducing effect in human lung squamous cell carcinoma and to selectively inhibit human neuroectodermal tumor growth in an in vivo experiment. Biochemical evidence for the apoptotic action of aloe-emodin in that aloe-emodin-treated C127 cells showed activation of caspase-3, caspase-8, and caspase-9 and increased relative abundances of cytochrome c in the cytosolic fraction. This cytochrome c increase resulted in mitochondrial death and finally C127 cell death.

In spite of these biologic activities, anthraquinones also have harmful effects, such as genotoxic, mutagenic, and tumor-promoting effects. Therefore, caution should be exercised with regard to the anthraquinones, and further studies need to be undertaken to more accurately define the activities of each component.

Saccharides

Aloe is a rich source of polysaccharides and has various carbohydrate constituents, for example, polysaccharides, acemannan, and mannose-6-phosphate, of which mannose-6-phosphate and acemannan are major constituents of the carbohydrates of aloe vera. Since mannose-6-phosphate is the major sugar in aloe vera gel, it was studied to determine whether it is an active
wound-healing and antiinflammatory ingredient in aloe vera. Mice receiving 300 mg/kg of mannose-6-phosphate had improved wound healing over saline controls. Grey et al. suggested that mannose-6-phosphate linked to a protein produce even greater wound-healing effects.

Acemannan (ie, aloe polymannose, a polydispersed β-(1,4)-linked acetylated mannose-containing complex carbohydrate) was found to have immunomodulatory activity. It was reported to activate macrophages; enhance cytokine release; stimulate interactions between macrophages, T-lymphocytes and B-lymphocytes; and enhance the generation of cytotoxic T-lymphocytes. Acemannan was also found to potentiate antibody production against coxsackie virus and reduce radiation-induced skin reactions in C3H mice. Acemannan enhanced the allo responsiveness of human lymphocytes and induced the phenotypic and functional maturation of immature dendritic cells. It also upregulated phagocytosis and the candidoidal activity of macrophages. Regarding its mechanism, acemannan induced no synthesis, which was mediated by macrophage mannose receptors in chickens, stimulated the synthesis of monokines, and initiated immune response. It also showed inhibitory effects on tumor growth, that is, murine sarcoma implanted in mice regressed after acemannan treatment, which was probably due to an immune attack and enhanced immunomodulation.

The ability of aloe vera to stimulate the immune system is attributed to polysaccharides present in the aloe vera gel. There has been some disagreement concerning the identities of the active materials, thus, the optimal form and composition of the aloe polysaccharides has been investigated to maximize immunomodulatory activity and stability. In one study the immunomodulatory activity of aloe vera was found to be caused by a 15 kDa polysaccharide, while modified aloe polysaccharide with an average molecular weight of 80 kDa showed the highest protective activity against UVB irradiation-induced immune suppression. The native polysaccharide is of 2000 kDa with a mannose:galactose:glucose ratio of 11:0.2:1, whereas the active form is of 80 kDa with mannose:galactose:glucose ratio of 40:1.4:1. The active polysaccharide is composed of mannose at a high ratio. Polysaccharides are also known to possess antitumor effects. A high molecular weight polysaccharide (aloeide) was found to have potent immunostimulatory activity, and was found to induce the expression of mRNAs encoding IL-1β and TNF-α. These polysaccharides may exhibit antitumor and antiviral activities through enhanced immune attack and immunomodulation.

Carcinogenesis induced by DNA adduct formation was shown to be inhibited by a polysaccharide-rich aloe gel fraction in an in vitro rat hepatocyte model. Kim et al. reported on the chemopreventive effect of aloe polysaccharide isolated from aloe vera noting that oxidative DNA damage assessed by 8-hydroxyguanosine was significantly reduced by the polysaccharide, which also inhibited benzo[a]pyrene-DNA adduct formation by interfering with benzo[a]pyrene-DNA absorption in vitro. This may be due to the inhibition of carcinogen activation systems or to the induction of detoxifying enzymes.

Cutaneous exposure to high doses of UVB radiation induces the systemic suppression of contact hypersensitivity responses to hapten applied to non-irradiated sites and of delayed-type hypersensitivity responses to infectious agents. UVB radiation contributes to the growth of highly antigenic skin cancers by suppressing T-cell mediated immune responses. Therefore, susceptibility to UV-induced immune suppression of contact hypersensitivity responses may be a risk factor for the development of skin cancer in humans.

Therapeutic intervention to prevent immune suppression may reduce the risk of skin cancer. Aloe oligosaccharides and polysaccharides were found to inhibit UV-induced immune suppression and interleukin-10 production. Aloe oligosaccharides may prevent UV-induced suppression of delayed-type hypersensitivity by reducing keratinocyte derived immunosuppressive cytokines. It is also suggested that aloe oligosaccharide protects against delayed type hypersensitivity response indirectly by inducing immunostimulatory cytokines, such as interleukin-12.

The latable natures of factors that prevent immune suppression vary in different gel extract preparations and is possibly influenced by the manufacturing process used. Variable activities in the reported experiments possibly result from the degradation of polysaccharide resulting from bacterial contamination or endogenous enzyme activity in aloe vera gel. These explain some of the difficulties that investigators have experienced in terms of result reproducibility when using unprocessed leaf gel from aloe vera.
Other Low-Molecular-Weight Components

In addition to the aforementioned components, low-molecular-weight components, such as aloe
sin, β-sitosterol, diethylhexylphthalate, and immunomodulatory substances have been examined.
Aloesin, a chromone derivative isolated from aloe vera, was found to enhance cell proliferation
by upregulating cyclin E/CdK2 kinase activity via inducing cyclin E, Cdk2, and Cdk2SA, in SK-
Hep-1 cells.22 Aloesin and arbutin were found to inhibit mushroom-tyrosinase activity in vitro in a
synergistic manner, which is an important element in medin synthesis.79 They inhibit tyrosi-

nase activity via different mechanisms in the sk-
Med-1 cell line; aloesin inhibits human tyrosinase activity via a noncompetitive inhibition mech-
nanism, whereas arbutin works via a competitive inhibition mechanism.79

Based on the wound-healing effect of aloe vera, the angiogenic component was isolated using an
activity-guided fractionation from aloe vera gel.80,81 A low-molecular-weight component from the
dichloromethane extract of freeze-dried aloe vera gel was shown to stimulate blood vessel forma-
tion in a chick choioallantoic membrane.82 Moreover, a methanol-soluble fraction of the gel stimu-
lated the proliferation of artery endothelial cells in an in vitro assay, and induced them to invade a
collagen substrate.83 The active component was found to be β-sitosterol, which showed a dose-de-
dependent angiogenic effect in a chick embryo choioallantoic membrane assay.79 β-sitosterol en-
hanced new vessel formation in Mongolian gerbil brain damaged by ischaemia/reperfusion, especially
in the cingulated cortex and septal areas.79 It also enhanced the expression of proteins related to
angiogenesis, namely the von Willebrand factor, vascular endothelial growth factor (VEGF), and VEGF
receptor Flk-1.79 Morisaki et al80 suggested that sterol structure be responsible for the angiogenic activity.
β-sitosterol was also found to have anti-inflammatory effects in wounded mice.4 Taking into account its unique activity, β-sitosterol can be viewed as another component that contributes to
the wound-healing effect of aloe vera.

Diethylhexylphthalate isolated from aloe vera induced apoptosis and was found to possess antitumor
and antimutagenic effects.81 CD95-mediated apoptosis is supposed to be a major effect
pathway by diethylhexylphthalate, but this detailed mechanism has not been widely studied.83

Aloe vera gel contains low-molecular-weight immunomodulators (ie, G1C2F1), which restore
UVB-suppressed accessory cell function of epidermal Langerhans cells both in vivo84 and in vitro.85 Exposure of the shaved abdominal skin of mice to UVB irradiation resulted in suppression of contact sensitization through the skin. Although treatment with G1C2F1 prevented UVB-induced suppression of contact sensitization in a dose-dependent manner, the irradiated skin of G1C2F1-treated groups showed similar levels of sunburn when examined on the day of sensitization.86 This may indicate that G1C2F1 prevent-UVB-induced elimination or functional alteration of epidermal Langerhans cell through a mech-
nanism that does not alter the initial inflammatory response and release of proinflammatory cytokines.85

CONCLUSION

Aloe vera contains many physiologically active substances that have effective antiinflamma-
tory, immunomodulatory, and wound-healing effects. The active ingredients, whether acting alone
or in concert, include glycoproteins, antirnnu-
nones, polysaccharides, and low-molecular-weight species. Moreover, the fact that biologically active
components in aloe vera may be labile, varied, or modified explain some of the difficulties that inves-
tigators have reported in reproducing results using unfractionated materials from aloe vera. In light of
the many pharmacologic activities of the components of aloe vera, each active component has sev-
eral interacting factors, each of which may be af-
fected by another substance(s). Thus, a further understanding of these individual components and
of their effects is essential if aloe vera is to be
successfully developed for therapeutic purposes.
